## A Comparison of Alternative Models for Estimating School Performance in Mathematics and Reading/Language Arts in Four State Accountability Systems: North Carolina Results

## Background and Introduction

This technical report is one of a series of four technical reports that describe the results of a study comparing eight alternative models for estimating school academic achievement using data from the Arizona, North Carolina, Oregon, and Pennsylvania accountability systems. Our purpose was not to evaluate or examine the accountability systems in use by these states, but to evaluate a broader range of models commonly used for estimating school performance that are applied in many states and frequently reported in the school effectiveness research literature. This introduction briefly describes the study background and details the methods and procedures we used to estimate the eight school performance models and compare model results in all four states. The individual state technical reports including details on each state's accountability data, assessment instruments, and results are provided at: http://www.ncaase.com/publications/techreports.

Despite the central importance of analytic models used in evaluating teacher and school effects in modern accountability systems, there are relatively few studies of the reliability and validity of these high-stakes systems (see, for example, Goldschmidt, Choi, \& Beaudoin, 2012). The results reported here examine eight models using operational state accountability data in mathematics and reading/language arts from the four participating states. We addressed four questions surrounding the use of analytic models for the evaluation of school performance:

1. Are estimates of school performance stable across successive cohorts of students?
2. How well do estimates of school performance correlate among models?
3. How do estimates of school performance correlate with variables describing the student composition of the school?
4. Do estimates of school performance vary from one model to another based on the school composition of students with disabilities (SWD)?

## General Method Description

## Sample

The sample from each state is described in each individual state technical report. In three of the four states, the sample consisted of all students who took the state's mathematics or reading/language arts general assessment in any one school year from 2007-08 through 2011-12, and whose records in each year were included in the state's calculation of Adequate Yearly Progress (AYP). Samples were separated into two grade level bands: a longitudinal elementary school sample (Grades 3 through 5) and a longitudinal middle school sample (Grades 6 through 8), each consisting of three cohorts (a) 2007/08 through 2009/2010; (b) 2008/09 through 2010/11; and (c) 2009/10 through 2011/12 (see research design schematic below). In Arizona, only one elementary and middle school cohort was used (2006/07 through 2008/09) due to changes in the Arizona testing program in 2010.

## Instruments

The outcome measures for all analyses were the standardized mathematics and reading/language arts tests used for accountability in each state. In three of the states, the instruments used vertically linked developmental scales created using item response theory (IRT)
methods. In Pennsylvania, the test was not vertically linked over grades preventing the estimation of certain school performance models described in the next section. More detail about the North Carolina test is contained in a later section of this report.

Research design indicating academic years and longitudinal cohorts studied:

| Grade | Academic Year |  |  |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $2007 / 08$ | E1 | E2 | E3 |  |  |  |  |  |
|  |  | E1 | E2 | E3 |  |  |  |  |  |
| 4 |  |  | E1 | E2 | E3 |  |  |  |  |
| 5 |  | M1 | M3 |  |  |  |  |  |  |
| 6 |  | M1 | M2 | M3 |  |  |  |  |  |
| 7 |  |  | M1 | M2 | M3 |  |  |  |  |

Note. E denotes an elementary school cohort, M denotes a middle school cohort. Only one elementary and one middle school cohort were available in the Arizona data.

## School Performance Models

For all models, we estimated school performance in the last focal year (Grade 5 or 8 ) of the two grade level bands, as well as using prior years of achievement data as dictated by the particular model. We applied eight alternative analytic models of school performance to the mathematics and reading/language arts achievement data in elementary and middle school for each state. The eight school performance models were: Percent Proficient (PP), gain score (Gain), transition matrix (TM), student growth percentile (SGP), value-added model (VAM), and three Multilevel Linear Model (MLM) estimates: focal year intercept or status (MLM0), focal year growth rate (Grate), and average MLM growth rate across the three years (AvGrate).

Percent Proficient (PP). PP was the NCLB required metric used by the state that calculated the percentage of students in each school that met or exceeded state benchmarks for proficiency in either mathematics or reading/language arts in each grade.

Average Gain Score. Gain scores were calculated as the prior academic year (Grade 4 or Grade 7) scale score in mathematics or reading/language arts subtracted from the focal year scale score (Grade 5 or Grade 8):

$$
\begin{equation*}
\text { Gain }_{\mathrm{i}}=\Delta_{\mathrm{i}}=\mathrm{Y}_{\mathrm{it}}-\mathrm{Y}_{\mathrm{i}(\mathrm{t}-1)} \tag{1}
\end{equation*}
$$

where $Y_{\text {it was }}$ wassessment outcome for student $i$ at time $t$. Student gain scores were averaged for each school (labeled "Gain" below).

Transition Matrix (TM). School performance estimates were computed from a table of the state's proficiency categories in the prior year crossed with the proficiency categories in the focal year (Grade 5 or Grade 8) which, in the case of five proficiency categories, created a transition matrix table of 25 cells. The percentage of students occurring in each of the cells was entered and then a weighting scheme was applied to each cell and the products were summed to create a TM school performance index. The weighting scheme awarded one of three scores: (a) -1 was recorded if the student moved down one or more categories from the previous year, (b) 0 was recorded if the student stayed in the same category, and (c) +1 was recorded if the student moved up one or more categories from the previous year (see Tindal, Nese, \& Stevens, 2017). The weighted values were averaged across all cells to create an overall school TM index.

Student Growth Percentiles (SGP). Student growth percentiles were computed at the student level using the approach described by Betebenner (2009). A student's SGP was calculated by taking the current year test score and regressing it on the two prior years of test scores. Betebenner's (2009) approach uses ordinal methods (quantile regression) as well as Bspline, cubic polynomial smoothing of the resulting normative distribution of conditional regression estimates. The analysis results in a relative rank for each student in a conditional distribution of those who had similar scores in previous years. We used the R package $S G P$ (Betebenner, \& Iwaarden, 2011) to compute student estimates based on the regression of the two prior years of test scores on the current year's test score and then we aggregated student SGP for each school to create a median SGP as each school's SGP performance estimate.

Value-added Models (VAM). This mixed effects approach examined performance gains over years and included indicators for student membership in a particular school. This model is known generally as the "layered model" because layers of equations are added with each year of schooling (Ballou, Sanders, and Wright, 2004). For example, the model for our case with students with three years of data would be specified as follows:

$$
\begin{align*}
& Y_{0 i j}=b_{0}+u_{0}+e_{0}  \tag{2a}\\
& Y_{1 i j}=b_{1}+u_{0}+u_{1}+e_{1}  \tag{2b}\\
& Y_{2 i j}=b_{2}+u_{0}+u_{1}+u_{2}+e_{2}, \tag{2c}
\end{align*}
$$

where $Y_{t i j}$ represents an assessment for student $i$ at time $t$ (grade) attending school $j$. The fixed mean for all students in the combination of grades and schools was $\mu_{t i j}$, while $e_{t i j}$ was the random deviation for student $n$ from the mean, $\mu_{t i j}$. The layered model we used was limited to a maximum of three years and was applied separately to mathematics and reading/language arts.

## Multilevel Linear Growth Model Initial Status, Focal Year Growth, and Average

 Growth (MLM0, MLM Growth Rate and MLM Average Growth Rate). We modeled student growth over the three elementary or three middle school grades with multilevel longitudinal analyses (Raudenbush \& Bryk, 2002) using HLM 7.1 (Raudenbush, Bryk, Cheong, Congdon, \& du Toit, 2011) and full maximum likelihood estimation. The conditional models included a level-1 model that specified student mathematics or reading/language arts scores predicted by a quadratic function of time of measurement, a level-2 model composed of the prediction of level1 model parameters as a function of student mean values, and a level-3 model composed of the prediction of level-2 parameters as a function of school mean parameter values. Time wascentered on the focal year (Grade 5 or 8 ) for computation of MLM0 and MLM growth rate but was centered on the middle year (Grade 4 or 7) for computation of MLM average growth rate. We used a quadratic model based on previous findings (Bloom, Hill, Black, \& Lipsey, 2008) as well as inspection of the data and statistical testing of alternative growth functions. Because only three time points were present, the model intercept and linear slope were random parameters but the variance of the quadratic parameter was fixed (note the omission of a residual term in equation 4 c below) to obtain a model solution. We used two different centering definitions to take into account the curvilinear nature of growth. Although centering in the last, focal year is most consistent with the definition of other models we examined, it likely underestimates the amount of growth that occurs over the three year period because of deceleration. We therefore also centered on the middle grade in the three year span to produce an average growth rate over the three years. The resulting MLM model equations were:

Level 1 (Time):

$$
\begin{equation*}
\left(Y_{t i j}\right)=\pi_{0 i j}+\pi_{1 i j}\left(\operatorname{time}_{t i j}\right)+\pi_{2 i j}\left(\text { time squared }_{t i j}\right)+e_{t i j} \tag{3}
\end{equation*}
$$

Level 2 (Students):

$$
\begin{align*}
& \pi_{0 i j}=\beta_{00 j}+r_{0 i j}  \tag{4a}\\
& \pi_{l i j}=\beta_{10 j}+r_{l i j}  \tag{4b}\\
& \pi_{2 i j}=\beta_{20 j} \tag{4c}
\end{align*}
$$

Level 3 (Schools):

$$
\begin{align*}
& \beta_{00 j}=\gamma_{000}+u_{00 j}  \tag{5a}\\
& \beta_{10 j}=\gamma_{100}+u_{10 j}  \tag{5b}\\
& \beta_{20 j}=\gamma_{200}+u_{20 j} \tag{5c}
\end{align*}
$$

where $Y_{t i j}$ was the mathematics or reading/language arts scale score for student $i$ at time $t$ in school $j$, $\pi_{0 i j}$ was the initial status or intercept for student i at time 0 in school $j, \pi_{1 i j}$ was the linear rate of change, $\pi_{2 i j}$ was the quadratic curvature representing the acceleration or deceleration in each student's growth trajectory and $e_{t i j}$ was the residual for each student. At level-2, the level-1 parameters were modeled using mean parameter values across students ( $\beta_{k 0 j}$ ) and at level-3, the level-2 parameters were modeled using mean parameter values across schools $\left.\left(\gamma_{k j}\right)^{\prime}\right)$.

## Comparison of Model Estimates

We used several comparison criteria to evaluate the comparability and stability of school estimates across school performance models and across cohorts. In each state technical report we describe the results of our evaluation of school performance estimates. We examined: (a) correlations of model estimates for each school across the three cohorts, (b) correlations among school estimates from one model to another, (c) correlations among the school estimates and school composition variables (e.g., percent free/reduced lunch in the school, percent minority students in the school), and (d) correlations of each model with the percentage of students with disabilities in the school.

## Comparison of School Ranks Based on Model Estimates

Many states and districts create school ranks based on their accountability system results. To compare the alternative school performance models using this metric, we created school
percentile ranks (from 1 to 99 , with 99 being the highest performance) based on each of the school performance model estimates described above. In one of the only studies evaluating school performance models, Goldschmidt, Choi, and Beaudoin (2012) compared models using quintiles. They examined the percentage of times schools remained in the same quintile band based on one school performance model versus another. Similarly, Castellano and Ho (2013) compared SGP and conditional regression models by examining the percentage of times schools remained within 1,5 or 10 percentile ranks for each model. To maintain some comparability with each of these studies, we used three levels of similarity in school ranks, computing the percentage of schools within 5,10 , or 20 ranks of each other. We also computed the Spearman's correlation of school ranks from one cohort to another or from one school performance model to another. As a final comparison metric, we computed the root mean squared difference (RMSD) between school ranks based on each pair of cohorts or each pair of school performance models (see Castellano \& Ho, 2013):

$$
\begin{equation*}
R M S D_{c, c}=\sqrt{\frac{\sum_{j=1}^{j}\left(\text { Rank }_{j c}-\text { Rank }_{j c}\right)^{2}}{n}} \tag{6}
\end{equation*}
$$

In equation 6, for a particular school performance model, the RMSD computes the difference ( Rank $_{i t}$ ) between each school's rank in one cohort ( $j t$ ) versus the school's rank in a second cohort (ju), squaring the difference, summing across all schools, dividing by the number of schools, $n$, and taking the square root of the result.

$$
\begin{equation*}
R M S D_{m n}=\sqrt{\frac{\sum\left(\text { Rank }_{j m}-\text { Rank }_{j n}\right)^{2}}{n}} \tag{7}
\end{equation*}
$$

Similarly, in equation 7, the school ranks arising from alternative school performance models are compared in which $\operatorname{Rank}_{j m}$ and $\operatorname{Rank}_{j n}$ represent the rank of school $j$ using school performance model m compared to that school's rank using school performance model $n$. As in equation 6, differences in ranks are then summed, squared, divided by the number of schools and taken to the $1 / 2$ power. The RMSD was a measure of similarity in school performance models where a lower value indicates a pair of models that rank schools most similarly.

## Summary

We evaluated eight models for estimating school academic performance in mathematics and reading/language arts using operational state accountability data. In NC, OR, and PA, we examined stability in model estimates across three successive student cohorts in mathematics and reading/language arts in both elementary and middle school grades. In all four states, we also compared the estimates of school performance from one model to another to determine whether the models provided similar or different depictions of school performance, although several models could not be estimated in Pennsylvania because their test did not have a vertically linked score scale. We then compared the degree to which model estimates correlated with variables that described the student composition of the school, a likely indication of construct irrelevant variance. Ideally estimates of school performance should not be related to the student composition of the school. Last, we evaluated the school performance models in terms of the way they ranked schools, the stability of school ranks across cohorts, and the degree of
agreement in school rankings from one school performance model to another. Detailed results of these analyses and comparisons follow for the state of North Carolina.

## North Carolina Study

## Method

## Sample

The North Carolina sample was separated into an elementary school sample (Grades 3 through 5) and a middle school sample (Grades 6 through 8), each consisting of three successive cohorts of students enrolled in school years: (a) 2007/08 through 2009/2010; (b) 2008/09 through $2010 / 11$; and (c) 2009/10 through 2011/12. The initial sample included students across the three cohorts whose Grade 5 (elementary school sample) or Grade 8 (middle school sample) North Carolina End-of-Grade reading comprehension or mathematics scores on the general or alternate assessment were included in the state calculation of Adequate Yearly Progress (AYP).
There was a small number of cases where a unique student identifier appeared to have been associated with more than one student in a year. When conflicting reading or mathematics scores were associated with a student identifier, all records were removed for that student identifier in that year. The initial elementary school sample for the mathematics test was 335,071 students. The initial middle school sample for the mathematics test was 317,015 students. The initial elementary school sample for the reading comprehension test was 334,684 students. The initial middle school sample for the reading comprehension test was 316,669 students.

To create an analytic sample that was appropriate for our research questions, we only included students with valid test scores in all three years in schools that served all three grades (Grades 3 through 5 or 6 through 8). Students who did not follow the typical grade level sequence due to grade retention, acceleration, or dubious progressions were excluded from the sample; this included the transition from 2006/07 to 2007/08, so that no students present in 2007/08 had been retained or accelerated from the previous year. We included only schools that served all three grades for a cohort, and schools with $N \geq 10$ students in each of the three cohorts in the final reference year of the three-year grade level band (i.e., Grade 5 for elementary grades 3 to 5 and Grade 8 for middle grades 6 to 8 ). Students and schools that did not meet these criteria were excluded from analyses. As is the case in most operational and research applications of these models, we made no attempt to account for student mobility in years prior to the focal year or to make any attributions of "school effects" based on how many years the student had been in the focal year school. Our concern in creating the analytic sample was to maximize the interpretation of comparisons of the models rather than to ensure complete representativeness of the samples. These inclusion rules were applied to ensure that there were no differences in the analytic samples for different school models so that comparisons of school models were a function only of differences in the models and not the composition of the sample analyzed. The final elementary school analytic sample for the mathematics test was 230,492 students ( $68.79 \%$ of the initial sample). The final middle school analytic sample for the mathematics test was 224,492 students ( $70.81 \%$ ). The final elementary school analytic sample for the reading comprehension test was 228,492 students ( $68.27 \%$ ). The final middle school analytic sample for the reading comprehension test was 223,530 students ( $70.59 \%$ ).

Table 1 provides summary statistics describing the school-level analytical samples of North Carolina elementary and middle school students in the three cohorts for mathematics and reading comprehension. School composition variables reported in the table include the percent of English Language Learners (ELL), females, economically disadvantaged students (EDS), ethnic minorities, and students with disabilities (SWD). Although variation existed from cohort to cohort in sample demographic characteristics, generally the composition of the samples was quite similar across the three cohorts. One exception was a small, but consistent increase in the proportions of students who were EDS or racial/ethnic minorities across the three cohorts for both grade level bands. Also, a slightly greater percentage of SWD and English Language Learners (ELL) participated in the mathematics than the reading comprehension assessment across all cohorts and grade bands. There was much greater school level variation-as indicated by the values of the standard deviations in parentheses-in EDS and racial/ethnic minority student school composition than other student characteristics. It should be noted that when we refer to "school" composition, it references variables representing a particular cohort in each school in our analytic samples. Because we excluded students and schools to create our analytic samples, "total school" characteristics may differ slightly from the variables reported here.

Table 1
Proportion and Standard Deviation (in parentheses) of Student Subgroups for the North Carolina Analytical Samples by Content Area and Grade Level Band

## Instrument

The outcome measures for all analyses were the third editions of the North Carolina End-of-Grade Tests in Mathematics (EOG-M) and Reading Comprehension (EOG-RC), which are standardized, vertically scaled tests designed to measure the core content standards in the state curriculum (NC Department of Public Instruction, 2008, 2009). Both tests were in a multiplechoice format and were the primary assessments used in the state's school accountability model. EOG raw scores were converted to developmental scale scores based on the number of items answered correctly, taking item difficulty into account using the three-parameter logistic model of item response theory (IRT) methods and a vertical linking design over grades (NC Department of Public Instruction, 2008, 2009).

## Results and Discussion

This technical report is organized in three sections: Section A describes school performance model estimates, Section B describes school ranks, and Appendices provide additional detailed results.

## Section A: School Performance Estimates

Cohort stability. We first considered the stability of model estimates by computing the correlations among estimates across the three successive cohorts of students. It should be noted that cohort comparisons are both an indication of changes in the composition of students in the
school from one academic year to another as well as any other temporal changes that occur from one year to another including changes in policy, practice, instruction, or other factors that impact student test scores. Table 2 shows the correlation of model estimates across cohorts for mathematics and reading comprehension in the elementary school and middle school samples. As can be seen in Table 2, correlations generally ranged only from small to moderate for the model estimates (with the exception of the MLM0 and PP estimates) indicating some substantial instability in school performance estimates across cohorts. Correlations between adjacent years in the first two columns (cohort 1 with 2 or 2 with 3 ) are generally somewhat higher than the comparisons across two years (cohort 1 with 3 ). Although there is also some variation from elementary to middle school or from mathematics to reading/language arts, trends in cohort stability were fairly similar across content area and grade level band. To facilitate interpretation

Table 2
Correlations of School Performance Model Estimates Across Cohorts by Content Area and Grade Level Band

Elementary Schools

|  | Mathematics |  |  | Reading Comprehension |  |  |
| ---: | ---: | ---: | ---: | :--- | :--- | :--- |

| AvGrate | 0.551 | 0.523 | 0.355 | 0.632 | 0.618 | 0.539 |

## Middle Schools

|  | Mathematics |  |  |  | Reading Comprehension |  |  |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Model | 1 with 2 | 2 with 3 | 1 with 3 | 1 with 2 | 2 with 3 | 1 with 3 |  |
| PP | 0.794 | 0.745 | 0.703 | 0.875 | 0.871 | 0.842 |  |
| MLM0 | 0.889 | 0.872 | 0.846 | 0.921 | 0.910 | 0.902 |  |
| Gain | 0.522 | 0.553 | 0.440 | 0.205 | 0.149 | 0.275 |  |
| TM | 0.439 | 0.076 | 0.003 | 0.409 | 0.443 | 0.440 |  |
| SGP | 0.594 | 0.616 | 0.489 | 0.355 | 0.338 | 0.355 |  |
| VAM | 0.642 | 0.637 | 0.503 | 0.501 | 0.484 | 0.465 |  |
| Grate | 0.503 | 0.508 | 0.405 | 0.215 | 0.179 | 0.218 |  |
| AvGrate | 0.631 | 0.624 | 0.469 | 0.561 | 0.442 | 0.423 |  |

of the cohort results, we also averaged correlations across the two content areas and grade levels (see Table 3). It can be seen that the correlations across cohorts were largest for the two statusbased school performance measures (PP and MLM0) and noticeably lower for all other models that used two or three years of data to estimate school performance. The two rightmost columns of Table 3 show the overall mean and standard deviation across the cohort comparisons for each school performance model. The greatest agreement over cohorts, content, and grade level was for the MLM0 estimates (MLM focal year intercepts), closely followed by the PP model estimates. All remaining multiyear performance models had much greater instability. The standard deviation of correlations across cohort comparisons shown in the rightmost column of Table 3 also show the least variability over cohorts for the two status models and the greatest variability across cohort correlations for the Transition model followed by the AvGrate model.

Table 3
Average Correlations Across Content Area and Grade Level Band and Overall Mean and Standard Deviation (SD) Across the Three Cohort Comparisons

|  | 1 with | 2 with | 1 with |  |  |
| ---: | :---: | :---: | :---: | :---: | :---: |
| Model | 2 | 3 | 3 | Mean | SD |
| PP | 0.778 | 0.735 | 0.708 | 0.740 | 0.037 |
| MLM0 | 0.878 | 0.860 | 0.842 | 0.860 | 0.019 |
| Gain | 0.380 | 0.372 | 0.318 | 0.357 | 0.065 |
| TM | 0.388 | 0.309 | 0.240 | 0.312 | 0.091 |
| SGP | 0.438 | 0.437 | 0.361 | 0.412 | 0.049 |
| VAM | 0.520 | 0.506 | 0.412 | 0.479 | 0.059 |
| Grate | 0.351 | 0.341 | 0.280 | 0.324 | 0.048 |

| Mean | 0.541 | 0.514 | 0.451 | -- | -- |

Comparison of models. We computed the correlations of school performance estimates from one model to another within each of the three cohorts and then took the mean correlation across cohorts. Correlations of model estimates within each individual cohort are presented in Appendix A. Table 4 shows model correlations for mathematics and reading/language arts in the elementary school and middle school samples averaged over the three cohorts.

Table 4

## Correlations of School Performance Estimates Across Models by Content Area and Grade Level Band

Average Over Content Area and Grade Level Band

| Model | MLM0 | Gain | TM | SGP | VAM | Grate | AvGrate |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | :---: |
| PP | 0.905 | 0.057 | -0.043 | 0.471 | 0.521 | 0.065 | -0.091 |
| MLM0 |  | 0.018 | -0.086 | 0.471 | 0.534 | 0.043 | -0.012 |
| Gain |  |  | 0.777 | 0.737 | 0.746 | 0.929 | 0.564 |
| TM |  |  |  | 0.525 | 0.518 | 0.713 | 0.505 |
| SGP |  |  |  |  | 0.931 | 0.619 | 0.573 |
| VAM |  |  |  |  |  | 0.647 | 0.591 |
| Grate |  |  |  |  |  |  | 0.332 |

As evident in Table 4, substantial variability was present in the degree to which school performance estimates for one model were related to other models and the correlations among models varied by content area and grade level band. For example, the correlation between the MLM0 model and the Transition model ranged from -.570 to +.258 and between PP and MLM AvGrate ranged from -. 426 to +.257 . The least variation in model correlations across content area and grade level band was for the MLM and VAM models from +.483 to +.580 .

As shown in the last panel of Table 4, on average across content area and grade level band, the highest correlations were among the SGP and VAM models (+.931), the Gain and Grate models (+.929), and the MLM intercept (MLM0) with the PP model (+.905). The lowest correlations were between the PP and MLM average growth rate (AvGrate) models (-.091) and the MLM0 model and the Transition model (-.086). The average correlation of the two status models (PP, MLM0) with the remaining six multiyear models was only +.162 . Average correlations among the six multiple year models ranged from +.505 to +.931 with one exception, the correlation of the Grate and AvGrate models was only +.332 , with an average correlation among all six multiyear models of +.607 .

We also examined the degree to which school performance model estimates were consistent from one content area to the other. Table 5 shows model estimate agreement across content areas in each cohort as well as the average across the three cohorts. As presented in Table 5, correlations were generally higher between content areas in elementary than middle school. On average, correlations for the two status models (PP and MLM0) were greater than +.750 and higher than average correlations for the other models that ranged from +.135 to +.532 .

Table 5
Correlations of School Performance Model Estimates between Mathematics and Reading Comprehension by Grade Level Band in each Cohort and Averaged over Cohorts

| Elementary Schools |  |  |  |  |  |  |  |  |  |

Relation with school composition variables. We computed the correlation of model estimates with school composition variables to determine whether estimates were related to the aggregated student characteristics in each school. Table 6 shows the correlations of model estimates with school composition variables for mathematics and reading comprehension in the elementary school and middle school samples. Correlations of model estimates with school composition variables within each individual cohort are presented in Appendix B.

The rightmost column of Table 6 shows the average correlation of each school performance model with the school composition variables across all school composition variables. As can be seen, correlations of the status models, PP and MLM0, were negative and noticeably stronger than the correlations of the other school performance models with school composition variables. On average across content and grade level band, the correlation of the school composition variables was -0.253 for the PP model and -0.260 for the MLM0 model. In contrast, the average correlations of the school composition variables with the remaining models were quite low ranging from -0.064 to +0.130 . Thus there was relatively little relation of the multiyear models with school composition, but for the status models performance estimates were higher when fewer students from protected subgroups were present in the school. No clear pattern was present for the relation between school size and model estimates.

Table 6

Relation of model estimates to SWD school composition. Because of the NCAASE emphasis on the performance and academic growth of SWD, we also focused more specifically on the relations between the percentage of SWD students served by a school and the school performance model estimates. Correlations of model estimates with SWD school composition within each individual cohort are presented in Appendix C. Table 7 shows the correlation of model estimates with the percentage of SWD in each school for mathematics and reading/language arts in the elementary school and middle school samples averaged over cohorts. As can be seen in the bottom row of Table 7, average school performance estimates based on the single-year, status models (PP and MLM0) had correlations with school SWD composition that were substantially stronger in magnitude than the other school performance models. With the PP and MLM0 models, school performance estimates were higher the smaller the percentage of SWD students in the school and lower to the extent that the school served larger proportions of SWD.

Table 7

Summary of Section A. We evaluated eight alternative models for estimating school academic performance in mathematics and reading/language arts using operational North Carolina state accountability data. We observed substantial variability in model estimates across three successive student cohorts in mathematics and reading/language arts in both elementary and middle school grades. Variability across cohorts was considerably less for the two status models (PP and MLM0) than for the models that used more than one year of data. We also compared the estimates of school performance from one model to another and found substantial disagreement across models. In general, correlations within model type (i.e., single year or multiyear) were stronger than correlations where a status model was paired with a model using multiple years of data.

We also compared school performance estimates in mathematics with those in reading/language arts. Again, agreement was greater across content areas for the status models than for the multiple year models. The correlations of the status models (PP and MLM0) with student composition were stronger than the correlations of the multiple year models with student composition. Larger proportions of protected student subgroups were associated with lower school performance. Finally, we correlated school performance estimates with the percentage of SWD in each school. Ideally, estimates of school performance should be unrelated to the student composition of the school, but as with the other school composition variables, we found that the status models were more strongly correlated with SWD school composition than the multiyear model estimates.

## Section B: School Ranks Based on School Performance Estimates

In this section, we focus on the examination of school ranks based on the school performance estimates reported in the previous section. It is a common practice for states and other jurisdictions is to rank schools as a method for evaluating academic performance. Therefore, using the estimates of school performance generated by the eight models described previously, we computed percentile ranks for each school. We then compared school ranks within each school performance model across the three cohorts used in the study. Next, we compared the school ranks for each model to the ranks obtained from each of the other models. Finally, we examined the relation between school ranks from each model with variables describing the student composition of each school. Three criteria were used to evaluate the comparisons of school ranks: (a) the Spearman's correlation between school ranks, (b) the proximity of absolute school ranks, and (b) the root mean square difference (RMSD) in school ranks.

Comparison of cohorts. We first consider the stability of school ranks within each school performance model across the three successive cohorts of students in mathematics and reading/language arts in the elementary and middle school grades. We computed the Spearman's correlation of the school ranks from one cohort to the school ranks from each of the other two cohorts within each of the eight school performance models to determine the stability of school ranks. As mentioned in Section A, cohort comparisons are both an indication of changes in the composition of students in the school from one academic year to another as well as any other temporal changes that occur from one year to another including changes in policy, practice, instruction, or other factors that impact student test scores. Table 8 shows the correlation of school ranks across cohorts for mathematics and reading/language arts in the elementary school and middle school samples. As can be seen in Table 8, the majority of the correlations fell in the moderate range indicating considerable variability in school ranks from one cohort to another. As would be expected, correlations between adjacent years in the first two columns (cohort 1 with 2 or 2 with 3 ) were generally somewhat higher than the comparison across two years (cohort 1 with 3). Results for mathematics tended to be more similar to those for reading in the elementary grades than the middle grades, and correlations in school ranks were more similar in the middle grades than the elementary grades.

Table 8
Spearman's Correlations of Model School Ranks for Each Pair of Cohorts by Content Area and Grade Level Band

## Elementary Schools

|  | Mathematics |  |  | Reading Comprehension |  |  |  |
| ---: | :--- | :--- | :--- | :---: | :---: | :---: | :---: |
| Model | 1 with 2 | 2 with 3 | 1 with 3 | 1 with 2 | 2 with 3 | 1 with 3 |  |
| PP | 0.726 | 0.693 | 0.653 | 0.724 | 0.650 | 0.655 |  |
| MLM0 | 0.816 | 0.782 | 0.748 | 0.861 | 0.837 | 0.837 |  |
| Gain | 0.414 | 0.436 | 0.307 | 0.325 | 0.316 | 0.237 |  |
| TM | 0.365 | 0.374 | 0.273 | 0.279 | 0.303 | 0.229 |  |
| SGP | 0.486 | 0.443 | 0.329 | 0.309 | 0.318 | 0.260 |  |
| VAM | 0.518 | 0.482 | 0.355 | 0.400 | 0.379 | 0.309 |  |
| Grate | 0.380 | 0.417 | 0.290 | 0.269 | 0.248 | 0.212 |  |
| AvGrate | 0.539 | 0.498 | 0.348 | 0.612 | 0.603 | 0.526 |  |

## Middle Schools

|  |  |  |  |  |  |  |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Mathematics |  |  | Middle Schools |  |  |
| Model | 1 with 2 | 2 with 3 | 1 with 3 | 1 with 2 | 2 with 3 | 1 with 3 |
| PP | 0.805 | 0.753 | 0.733 | 0.873 | 0.857 | 0.838 |
| MLM0 | 0.880 | 0.854 | 0.827 | 0.911 | 0.898 | 0.893 |
| Gain | 0.488 | 0.492 | 0.405 | 0.212 | 0.168 | 0.245 |
| TM | 0.444 | 0.059 | 0.003 | 0.440 | 0.474 | 0.436 |
| SGP | 0.565 | 0.574 | 0.448 | 0.360 | 0.368 | 0.349 |
| VAM | 0.618 | 0.607 | 0.477 | 0.476 | 0.478 | 0.468 |
| Grate | 0.469 | 0.455 | 0.379 | 0.205 | 0.164 | 0.215 |
| AvGrate | 0.592 | 0.593 | 0.437 | 0.543 | 0.444 | 0.435 |

To facilitate further interpretation, we averaged the results shown in Table 8 across content area and grade level band. As can be seen in Table 9, on average the greatest stability was for the two status models, PP and MLM0. Noticeably lower correlations occurred for the remaining school performance models, all of which were based on more than one year of data, with the least stability for the TM, Grate, and Gain models.

Table 9
Spearman's Correlations of Model School Ranks Averaged Across Content Area and Grade Level Band and Overall Mean and Standard Deviation (SD) Across the Three Cohort Comparisons

|  |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | :--- |
| Model | 1 with 2 | 2 with 3 | 1 with 3 | Mean | SD |
| PP | 0.782 | 0.738 | 0.720 | 0.747 | 0.033 |
| MLM0 | 0.867 | 0.843 | 0.826 | 0.845 | 0.021 |
| Gain | 0.360 | 0.353 | 0.298 | 0.337 | 0.051 |
| TM | 0.382 | 0.302 | 0.235 | 0.306 | 0.089 |
| SGP | 0.430 | 0.426 | 0.347 | 0.401 | 0.048 |
| VAM | 0.503 | 0.486 | 0.402 | 0.464 | 0.054 |
| Grate | 0.331 | 0.321 | 0.274 | 0.309 | 0.042 |
| AvGrate | 0.572 | 0.534 | 0.436 | 0.514 | 0.074 |

Our second criterion for comparing school ranks was to determine how much a school's rank changed from one cohort to another. Table 10 shows the proportion of schools that were within 5,10 , or 20 ranks in one cohort versus another for each school performance model in mathematics and reading/language arts at each grade level band. The last table entry for each school performance model shows the average differences in school ranks averaged over content area and grade level band. It can be seen that on average for the PP model, about one quarter to one third of the schools differed by only 5 percentile ranks or less, about half of schools differed by 10 ranks or less, and about $70-75 \%$ differed by 20 ranks or less. This also indicates that about $25 \%$ of schools differed by more than 20 ranks from one cohort to another. The results for the MLM0 model showed somewhat greater agreement in school ranks across cohorts. However, the level of agreement in school ranks across cohorts was noticeably lower for all of the remaining models that were based on two or more years of achievement data. For example, school ranks based on the remaining models (Gain, TM, SGP, VAM, Grate, and AvGrate) differed by more than 20 ranks for about $50 \%$ of the schools.

Table 10
Proportion of Elementary or Middle Schools Within 5, 10, or 20 Ranks of Each Other for Each School Performance Model for Each Pair of Cohorts in Mathematics and Reading Comprehension

## PP

|  | Cohort | $\mathrm{r}=5$ | $\mathrm{r}=10$ | $\mathrm{r}=20$ |
| :--- | :--- | :---: | :---: | :---: |

Our third criterion for comparing school ranks was to calculate the root mean square difference (RMSD) between cohorts or models as defined in the report introduction. Table 11 shows the RMSD across pairs of cohorts by content area and grade level band for each of the eight school performance models and in the last two columns the mean and standard deviation (SD) across cohort comparisons. As can be seen in the table, the smallest differences in rank were for the MLM0 model, about 12-18 ranks on average, followed by the PP model. Average differences in school rank across cohorts for the remaining models ranged from about 26 to 36 .

Table 11
RMSD in School Ranks for Each Student Cohort for Each School Performance Model by Content Area and Grade Level Band

Comparison of models. We next compared school ranks from one model to another within each of the three cohorts. We first computed the Spearman's correlations among school ranks for the different models. These values were quite similar to the Spearman's correlations among school model estimates (see Table 4 and Appendix A) and for this reason they are not included in this report. Our second criterion for comparing school ranks was to determine how much a school's rank changed from one model to another. For each pair of school performance models, Table 12 shows the average percentage of schools that were within 5,10 , or 20 percentile ranks in one model versus the other. As can be seen in the table, three pairs of models produced results that were quite similar: (a) SGP vs. VAM, (b) Gain vs. Grate, and (c) PP vs. MLM0. In each of these three pairings, over $74 \%$ of schools were within 10 ranks of each other and over $92 \%$ were within 20 ranks of each other.

When a single year model (PP or MLM) was paired with a model that made use of multiyear results, the level of agreement in school ranks was much lower than when a single year model was paired with another single year or status model (PP and MLM) or a multiyear model with a multiyear model.

Table 12
Proportion of Elementary or Middle Schools Within 5, 10, or 20 Ranks of Each Other for Each Pair of School Performance Models in Mathematics and Reading Comprehension Averaged Over Cohorts

Our last criterion for comparing school ranks across cohorts was the RMSD between pairs of school performance model rankings. Appendix E shows the RMSD between pairs of school performance model rankings for each individual cohort. Table 13 shows the RMSD averaged over the three cohorts by content area and grade level band. The RMSD values reflect the same patterns of results for models as described previously. The SGP vs. VAM, Gain vs. Grate, and PP vs. MLM0 pairings produced school rankings that were quite similar.

When a single year model (PP or MLM) was paired with a model that made use of multiyear results, the level of agreement in school ranks was much lower (difference of about 37 ranks on average across all model pairings of this type) than when the two single year models were paired (MLM and PP pairs differed by 11 ranks on average), or a multiyear model was paired with another multiyear model (difference of about 22 ranks, on average).

Table 13
Average Across Cohorts of RMSD in School Ranks Between School Performance Models by Content Area and Grade Level Band

| Grate |  |  |  |  |  |  | 36.362 |

We also evaluated the extent to which school ranks agreed from one content area to the other. Table 14 shows the Spearman's correlation of school ranks in mathematics with school ranks in reading comprehension by cohort and grade level band. The table also shows the mean correlation across cohorts at the two grade level bands. As can be seen in Table 14, on average correlations of school ranks across mathematics and reading comprehension in elementary schools ranged from about .33 to .92 for the different school performance models. For middle schools, the average correlations ranged from about .14 to .77. Correlations were higher for the two status models, and lower for the multiyear models at both grade level bands. Average correlations at the middle school level were lower than for the elementary level for all models.

Table 14
Spearman's Correlations of School Performance Model Estimates Across Mathematics and Reading Comprehension by Cohort

Table 15 shows the proportion of schools that shared similar ranks in mathematics as in reading comprehension for each school performance model by school level and averaged over grade level band. Similar to results previously described, Table 15 shows greater agreement for the PP and MLM0 models than the other school performance models with about $82 \%$ or more of the schools having ranks within 20 places across grade level bands. In contrast, there was substantially less agreement across the two content areas for the remaining, multiyear models with only approximately $50 \%$ of schools agreeing within 20 ranks for most models in either grade level band.

Calculation of the RMSD in school ranks for mathematics versus reading comprehension by cohort and grade level band and averaged over cohorts showed similar results (see Table 16). The difference in school ranks averaged over cohorts for the PP and MLM0 models ranged from about 8 to 19. Average differences in rank across the two content areas were substantially greater for the remaining models ranging from 28 to 37 depending on model and grade level band.

Relation with school composition variables. We computed the correlation of school ranks based on each school performance model with school composition variables to determine whether estimates were related to the aggregated student characteristics in each school. Table 17 shows these correlations for mathematics and reading comprehension in the elementary school and middle school samples. Correlations of model estimates with school composition variables within each individual cohort are presented in Appendix F. The rightmost column of Table 17 shows the correlation of each school performance model averaged over all of the school composition variables. As can be seen, correlations of the status models, PP and MLM0, ranged from -. 218 to -.303 depending on content and grade level band and were noticeably stronger in magnitude than the correlations of the other school performance models with school composition variables, which ranged from -.148 to +.218 depending on content and grade level band.

Relation of school ranks with SWD school composition. We specifically examined the relations between the percentage of SWD students served by a school and the school ranks based on the school performance model. Table 18 shows these correlations for mathematics and reading comprehension in the elementary school and middle school samples averaged over cohorts. Correlations of model estimates with SWD school composition within each individual cohort are presented in Appendix G. As can be seen in the bottom row of Table 18, on average, correlations of the status models (PP and MLM0) with school SWD composition were
substantially stronger in magnitude than the correlations for the other school performance models. With the PP and MLM0 models, school ranks were higher with lower percentages of SWD students in the school and school ranks were lower as schools served larger proportions of SWD. Little relation was present between school ranks based on the other models and SWD school composition.

Summary of Section B. We evaluated the school ranks arising from eight alternative models for estimating school academic performance in mathematics and reading comprehension across three sequential cohorts of students. As with the school performance estimates described in Section A, substantial variability in school ranks was present across the three student cohorts regardless of content area or grade level band. When we compared school ranks arising from one model to school ranks from other models, we found three pairs of models produced similar results across the members of a pair. Those models were (a) SGP and VAM, (b) Gain and Grate, and (c) MLM intercept (MLM0) and PP model. In general, pairs of models that combined a status model with a model making use of multiple years of test data showed the most discrepant results.

Comparison of model estimates to school composition variables showed that the status models (PP and MLM0) had correlations stronger in magnitude than the remaining school performance models. Finally, we correlated school ranks arising from the eight performance models with the percentage of SWD in each school. As with the school performance model estimates, we found the status models were more strongly correlated with SWD school composition but there was little relation of the other model estimates with the percentage of SWD students in the school.

## Conclusion

This report described the North Carolina results of a large study examining eight alternative methods of estimating school performance. The eight alternative methods were representative of types of models often used in state accountability models, although none were the actual model used in North Carolina at the time. We represented school performance in two
ways, the actual model estimates and school ranks based on model estimates. In addition to this North Carolina report, there are reports describing results for the three other states (AZ, OR, PA) included in the study. Our primary interest in these comparisons was estimating the impact of cohort and student composition (including the percent of SWD) on school performance estimates, as well examining the extent to which different estimates of school performance correlated with each other.

A number of general conclusions can be drawn from the results of the North Carolina analyses. First, model representations of school performance over successive cohorts of students were very unstable, irrespective of whether representations were based on school performance model estimates or on school ranks. There was somewhat greater stability for status models (PP, MLM0) than for the multiyear models. Nonetheless, even with the most stable model, MLM0, Spearman's correlations showed that less than $75 \%$ of the variance was common across cohorts, and over all the models, there was substantial instability over cohorts. These results were also reflected in the examination of differences in absolute or average (RMSD) differences in ranks over cohorts.

Our examination of the relations of the school performance models with each other produced similar results. Generally, there was agreement between the two status model estimates (PP and MLM0) that were based on a single year of data, but these two models did not agree with the remaining multiyear models. However, there was some substantial agreement of the multiyear models with each other with some variations. In general, the AvGrate model showed the least agreement with the other multiyear models.

We also examined the relation of school performance model estimates with variables describing the student composition of the schools. These results showed a pattern of results that differed between the status and the multiyear models. The two status models had substantially higher correlations with school composition variables than the multiyear models. This was also true in terms of the percentage of SWD students served by a school. The larger the percentage of SWD in the school, the lower the status model estimates of school performance.

Thus, the North Carolina results showed consistent patterns of instability of estimates of school performance over successive cohorts of students, different estimates of school performance depending on the model chosen, especially for status versus multiyear models, and stronger relations of status models with the student composition of the school than multiyear models. Taken together, these results suggest the need for substantial caution in the way that school performance models are used and interpreted. Cohort instability suggests that rolling averages or some other mechanism is needed to provide more dependable depictions of school performance that are more stable over time. The substantial disagreement among the school performance models suggests that the choice of model matters a great deal. This choice should be made very carefully. A single model estimate of school performance may not be trustworthy and may need to be augmented by the results from additional models or metrics of school performance.
