Abstract

easyCBM® is an online benchmark and progress monitoring assessment system designed for use within a response to intervention (RTI) framework. Part of the purpose of easyCBM® is to help educators identify students who may be at risk for academic failure. Often, students deemed at-risk are those who would be predicted to not pass the state test. Previous research has shown that educators using easyCBM® may classify students as at-risk or not for passing the Oregon state test with a high degree of accuracy. In this technical report, we report on an extension of this research, examining the relation between easyCBM® and the test used for accountability in Washington state. We conduct regression and correlation analyses to examine the relation between the measures, and use scatterplots to illustrate this relation with respect to cut scores.

easyCBM® Criterion-Related Validity Evidence: Washington State Test

In this technical report, we present the results of a study of the criterion validity of easyCBM® reading at grades 3-8. The Measures of Student Progress (MSP), Washington's state test used for accountability purposes, was used as the criterion. The MSP was administered at the end of the school year, while easyCBM® was administered tri-annually. Thus, we examine easyCBM® for both predictive validity evidence, with the fall and winter measures predicting the MSP, and for concurrent validity evidence, with the relation between the spring measure and MSP examined.

The easyCBM® Progress Monitoring Assessments

The online easyCBM® progress monitoring assessment system was launched in September 2006 as part of a Model Demonstration Center on Progress Monitoring funded by the Office of Special Education Programs (OSEP). At the time this technical report was published, 92,925 teachers had registered easyCBM® accounts, representing schools and Districts spread across every state in the country. During the 2008-2009 school year, an average of 305 new accounts were registered each week, and the popularity of the system continues to grow. In the month of October 2010, alone, 11,885 new teachers registered for accounts. The online assessment system provides both universal screener assessments for fall, winter, and spring administration and multiple alternate forms of a variety of progress monitoring measures designed for use in K-8 school settings. By design, alternate forms of the measures within a grade level are of comparable difficulty, whether they are deployed as progress monitoring or benchmarking assessments. Thus, although data for the analyses reported here were gathered specifically from the benchmark assessment forms, the findings should apply equally to the progress monitoring forms. Because the MSP is not administered prior to grade 3, we limit our

analyses in this technical report to the easyCBM® measures available for use in grades 3 through 8. In reading, these constructs include reading comprehension, oral reading fluency, and vocabulary.

As part of state funding for Response to Intervention (RTI), states need technically adequate measures for monitoring progress. Given the increasing popularity of the easyCBM® online assessment system, it is imperative that a thorough analysis of the measures' technical adequacy be conducted and the results shared with research and practitioner communities. This technical report addresses that need directly, providing the results of a study examining the predictive and concurrent validity evidence supporting the use of the easyCBM® assessments in reading in Washington state schools.

Methods

This study was conducted in the fall of 2010 using data provided by two public school districts from Washington state.

Setting and Subjects

The two public school districts that participated in this study were both located in the western half of Washington state. Data came from a convenience sample of students in each district who participated in the districts' benchmarking assessments in the fall of 2009 and the winter and spring of 2010. All analyses were conducted by grade level. Descriptive and correlation analyses were conducted both with the full sample and by District while the regression analyses were conducted only with the full sample to ensure a sufficient number of students to provide adequate statistical power.

Measures

In this section we first describe the easyCBM® reading measures and then provide

information about the Washington state test of reading. Additional information related to the test-retest and alternate form reliability of the easyCBM® reading assessments can be found in Alonzo and Tindal (2009).

Multiple Choice Reading Comprehension

The easyCBM® assessment system includes measures of reading comprehension (MCRC). Each MCRC measure consists of a 1,500 word original work of narrative fiction followed by 20 multiple-choice questions. Of the questions, 7 sample students' literal comprehension, 7 sample their inferential comprehension, and the final 6 sample their evaluative comprehension. Each question consists of a question stem followed by three possible answer choices: one correct, one intended as a near-distractor, and one intended as a far-distractor. The MCRC measures are designed to be group administered by computer, with automatic recording and scoring of student responses. Students score one point for every question answered correctly, for a total possible score of 20 points. Complete description of the development of the MCRC measures can be found in published technical reports (Alonzo, Liu, & Tindal, 2008; Alonzo & Tindal, 2008b).

Oral Reading Fluency

The easyCBM® assessment system includes two different measures of oral reading fluency: a word reading fluency (WRF) measure and a passage reading fluency (PRF) measure in grade 3. Beginning in grade 4 and extending through grade 8, only the PRF measure is available. Both measures of oral reading fluency are designed for individual one-on-one administration. The WRF consists of a chart of words, both decodable and irregular, presented on a single piece of paper. Test administrators have students read from this chart of words, moving from left to right and from the top to the bottom of the page, while they follow along on their own copy of

the assessment on which they mark every word read incorrectly. Students are given 60 seconds in which to read from the chart of words. Words students fail to read or read incorrectly are counted as errors. The final score, number of words read correctly per minute, is recorded in the easyCBM® assessment system. Complete description of the development of the WRF measures can be found in Alonzo and Tindal (2007).

The PRF measure consists of an original work of narrative fiction presented to students on a single sheet of paper. The PRF measures vary in length from 250 words (for younger grades) to 380 words (in middle school). As with the WRF measure, test administrators have students read from their copy of the measure, moving from left to right and from the top to the bottom of the page, while test administrators follow along on their own copy of the assessment on which they mark every word read incorrectly. Students are given 60 seconds in which to read. Words students fail to read or read incorrectly are counted as errors. The final score, number of words read correctly per minute, is recorded in the easyCBM® assessment system. Complete description of the development of the PRF measures can be found in Alonzo, Park, and Tindal (2008), Alonzo and Tindal (2008a), and Alonzo and Tindal (2007).

Vocabulary

The easyCBM® assessment system includes a measure of vocabulary for use as part of the fall and spring benchmark assessments. The measure consists of 25 multiple-choice questions. Each question consists of a question stem followed by three possible answer choices: one correct, one intended as a near-distractor, and one intended as a far-distractor. The vocabulary measures are designed to be group administered by computer, with automatic recording and scoring of student responses. Students score one point for every question correctly answered, for a possible score of 25 points. Complete description of the development of the

vocabulary measures can be found in Alonzo and Tindal (2004).

The MSP

The MSP was newly implemented for the 2009-2010 school year. Previously, Washington had administered the Washington Assessment of Student Learning, a longer test that was limited to paper pencil format. According to the Washington Department of Education, the MSP will eventually be a computer administered assessment; however, because this was the first year the assessment was administered, only about 25% of students in grades 6-8 were administered the assessment by computer. The state plans to move to a fully computer administered test within 2-3 years. The MSP includes multiple-choice and short answer item types.

Data Analysis

To examine the predictive and concurrent validity of easyCBM[®], we conducted regression and correlation analyses. Numerous regression models were tested at each grade level. First, a full model was run, which included all easyCBM[®] assessments administered throughout the year within a given grade. This model provided an indication of the total relation between easyCBM[®] and the MSP. Second, individual models were tested for each measure during each seasonal administration. Third, seasonal models were tested with each measure administered during a particular season. At grade three, a measure of word reading fluency was included in the full model. A subsequent “full model minus word reading fluency” model was then tested because while data were available for students in grade 3, the word reading fluency measure is typically only administered in grades K-2. Thus, while the measure was included in grade three as a test variable, it was not a primary variable of interest. The full model could not be computed at grades six and eight due to an insufficient number of students with full data across the

variables. At grade 8, the fall seasonal model could similarly not be computed.

Correlations are reported for both the full model and the individual models, by District and by the full samples. To visually represent the relation between easyCBM® and the MSP, and to examine the impact of cut scores, we also produced scatterplots for each measure during each seasonal administration with the full sample. On each scatterplot, students' MSP scores are plotted along the y-axis and their easyCBM® scores are plotted along the x-axis. The vertical lines on each plot represent the 20th and 50th percentiles of normative achievement on easyCBM®, while the horizontal line represents the cut score for the *meets standards expectations* performance level on the MSP.

Results

Descriptive statistics and correlations are reported for District 1 on pp. 15-20 and District 2 on pp. 21-32. Descriptive statistics and the results of the regression analyses are reported for the full sample by grade on pp. 33-178. Scatterplots for the full sample are reported by grade and measure on pp. 179-224. Overall, the full model accounted for between 53% and 62% of the variance in MSP scores.

At grade 3, the full model including WRF accounted for 60% of the total variance in MSP scores. Removing the measure of WRF decreased the overall variance accounted for by 1%, with the overall model accounting for 59% of the variance in MSP scores. In both models, the fall vocabulary measure was the largest predictor, uniquely accounting for 2.3% of the total variance in the model including the measure of WRF, and 2.4% of the total variance without the WRF measure. The fall and winter seasonal models, examined for predictive validity evidence, accounted for 52% and 44% of the total variance in MSP scores respectively. The spring model, examined for concurrent validity evidence, accounted for 54% of the variance in MSP scores.

At grade 4, the full model accounted for 56% of the total variance in MSP scores. The winter MCRC measure was the largest predictor, uniquely accounting for 6.7% of the total variance. The fall and winter models, examined for predictive validity evidence, each accounted for 34% of the variance in MSP scores. The spring model, examined for concurrent validity evidence, accounted for 46% of the variance in MSP scores.

At grade 5, the full model accounted for 62% of the total variance in MSP scores. The fall vocabulary measure was the largest predictor in the model, uniquely accounting for 1.6% of the total variance. The fall and winter models, examined for predictive validity evidence, accounted for 59% and 51% of the variance in MSP scores respectively. The spring model, examined for concurrent validity evidence, accounted for 55% of the variance in MSP scores.

At grade 6, the fall and winter models, examined for predictive validity evidence, accounted for 44% and 33% of the variance in MSP scores respectively. The spring model, examined for concurrent validity evidence, accounted for 57% of the variance in MSP scores. However, these results should be viewed with caution, as data from only 57 students were included in these analyses.

At grade 7, the full model accounted for 53% of the total variance in MSP scores. The spring vocabulary measure was the largest predictor in the model, uniquely accounting for 3.0% of the total variance. The fall and winter models, examined for predictive validity evidence, accounted for 52% and 33% of the variance in MSP scores respectively. The spring model, examined for concurrent validity evidence, accounted for 45% of the variance in MSP scores.

At grade 8, the winter model, examined for predictive validity evidence, accounted for 50% of the variance in MSP scores respectively. The spring model, examined for concurrent validity evidence, accounted for 73% of the variance in MSP scores. However, with data from

only 12 students included in the spring model, these results should be viewed with extreme caution.

Discussion

The results of this study suggest a strong relation between the easyCBM® reading measures and the MSP. An investigation of the scatterplots indicates that, even early in the year, very few students who scored below the 20th percentile on easyCBM® reached the *proficiency* performance level classification on the MSP. Above the 50th percentile, however, most students did reach the *proficiency* performance level classification, although overall it appears that easyCBM® is less accurate in predicting which students *will* reach proficiency than in predicting which students *will not* reach proficiency.

These findings add to the evidence that the easyCBM® reading measures are predictive of state large-scale assessments of reading, replicating findings reported from Oregon (Sáez et al., 2010) in earlier technical reports.
